

# Package: clifford (via r-universe)

October 23, 2024

**Type** Package

**Title** Arbitrary Dimensional Clifford Algebras

**Version** 1.0-9

**Depends** R (>= 4.1.0)

**Maintainer** Robin K. S. Hankin <hankin.robin@gmail.com>

**Description** A suite of routines for Clifford algebras, using the 'Map' class of the Standard Template Library. Canonical reference: Hestenes (1987, ISBN 90-277-1673-0, ``Clifford algebra to geometric calculus"). Special cases including Lorentz transforms, quaternion multiplication, and Grassmann algebra, are discussed. Vignettes presenting conformal geometric algebra, quaternions and split quaternions, dual numbers, and Lorentz transforms are included. The package follows 'disordR' discipline.

**License** GPL (>= 2)

**LazyData** yes

**Suggests** knitr,rmarkdown,testthat,onion (>= 1.5-3),lorentz (>= 1.1-1),emulator (>= 1.2-24),jordan (>= 1.0-5),permutations (>= 1.1-5),covr

**VignetteBuilder** knitr

**Imports** Rcpp (>= 0.12.5),disordR (>= 0.0-8),magrittr, methods, partitions (>= 1.10-4),freealg (>= 1.0-4)

**LinkingTo** Rcpp,BH

clifford-package	<i>Arbitrary Dimensional Clifford Algebras</i>
------------------	--

---

### Description

A suite of routines for Clifford algebras, using the 'Map' class of the Standard Template Library. Canonical reference: Hestenes (1987, ISBN 90-277-1673-0, "Clifford algebra to geometric calculus"). Special cases including Lorentz transforms, quaternion multiplication, and Grassmann algebra, are discussed. Vignettes presenting conformal geometric algebra, quaternions and split quaternions, dual numbers, and Lorentz transforms are included. The package follows 'disordR' discipline.

**Details**

The DESCRIPTION file: This package was not yet installed at build time.

Index: This package was not yet installed at build time.

**Author(s)**

**Examples**

```
as.1vector(1:4)

as.1vector(1:4) * rcliff()

# Following from Ablamowicz and Fauser (see vignette):
x <- clifford(list(1:3,c(1,5,7,8,10)),c(4,-10)) + 2
y <- clifford(list(c(1,2,3,7),c(1,5,6,8),c(1,4,6,7)),c(4,1,-3)) - 1
x*y # signature irrelevant
```

---

allcliff

*Clifford object containing all possible terms*

---

**Description**

The Clifford algebra on basis vectors  $e_1, e_2, \dots, e_n$  has  $2^n$  independent multivectors. Function `allcliff()` generates a clifford object with a nonzero coefficient for each multivector.

**Usage**

```
allcliff(n,grade)
```

**Arguments**

n	Integer specifying dimension of underlying vector space
grade	Grade of multivector to be returned. If missing, multivector contains every term of every grade $\leq n$

**Author(s)**

Robin K. S. Hankin

**Examples**

```
allcliff(6)

a <- allcliff(5)
a[] <- rcliff()*100
```

---

antivector

*Antivectors or pseudovectors*

---

**Description**

Antivectors or pseudovectors

**Usage**

```
antivector(v, n = length(v))
as.antivector(v)
is.antivector(C, include.pseudoscalar=FALSE)
```

**Arguments**

v	Numeric vector
n	Integer specifying dimensionality of underlying vector space
C	Clifford object
include.pseudoscalar	Boolean: should the pseudoscalar be considered an antivector?

## Details

An *antivector* is an  $n$ -dimensional Clifford object, all of whose terms are of grade  $n - 1$ . An antivector has  $n$  degrees of freedom. Function `antivector(v,n)` interprets `v[i]` as the coefficient of  $e_1 e_2 \dots e_{i-1} e_{i+1} \dots e_n$ .

Function `as.antivector()` is a convenience wrapper, coercing its argument to an antivector of minimal dimension (zero entries are interpreted consistently).

The pseudoscalar is a peculiar edge case. Consider:

```
A <- clifford(list(c(1,2,3)))
B <- A + clifford(list(c(1,2,4)))

> is.antivector(A)
[1] FALSE
> is.antivector(B)
[1] TRUE
> is.antivector(A,include.pseudoscalar=TRUE)
[1] TRUE
> is.antivector(B,include.pseudoscalar=TRUE)
[1] TRUE
```

One could argue that A should be an antivector as it is a term in B, which is definitely an antivector. Use `include.pseudoscalar=TRUE` to ensure consistency in this case.

Compare `as.1vector()`, which returns a clifford object of grade 1.

## Note

An antivector is always a blade.

[as.1vector](#)

## Examples

```
antivector(1:5)

as.1vector(c(1,1,2)) %X% as.1vector(c(3,2,2))
c(1*2-2*2, 2*3-1*2, 1*2-1*3) # note sign of e_13
```

---

`as.vector`*Coerce a clifford vector to a numeric vector*

---

**Description**

Given a clifford object with all terms of grade 1, return the corresponding numeric vector

**Usage**

```
## S3 method for class 'clifford'  
as.vector(x,mode = "any")
```

**Arguments**

<code>x</code>	Object of class clifford
<code>mode</code>	ignored

**Note**

The awkward R idiom of this function is because the terms may be stored in any order; see the examples

**Author(s)**

Robin K. S. Hankin

**See Also**

[numeric\\_to\\_clifford](#)

**Examples**

```
x <- clifford(list(6,2,9),1:3)  
as.vector(x)  
  
as.1vector(as.vector(x)) == x # should be TRUE
```

---

cartan	<i>Cartan map between clifford algebras</i>
--------	---

---

**Description**

Cartan's map isomorphisms from  $Cl(p, q)$  to  $Cl(p - 4, q + 4)$  and  $Cl(p + 4, q - 4)$

**Usage**

```
cartan(C, n = 1)
cartan_inverse(C, n = 1)
```

**Arguments**

C	Object of class <code>clifford</code>
n	Strictly positive integer

**Value**

Returns an object of class `clifford`. The default value  $n=1$  maps  $Cl(4, q)$  to  $Cl(0, q+4)$  (`cartan()`) and  $Cl(0, q)$  to  $Cl(4, q - 4)$ .

**Examples**

```
a <- rcliff(d=7) # Cl(4,3)
b <- rcliff(d=7) # Cl(4,3)
signature(4,3) # e1^2 = e2^2 = e3^2 = e4^2 = +1; e5^2 = e6^2=e7^2 = -1
ab <- a*b      # multiplication in Cl(4,3)

signature(0,7) # e1^2 = ... = e7^2 = -1
cartan(a)*cartan(b) == cartan(ab) # multiplication in Cl(0,7); should be TRUE

signature(Inf) # restore default
```

---

 clifford

 Create, coerce, and test for clifford objects
 

---

### Description

An object of class `clifford` is a member of a Clifford algebra. These objects may be added and multiplied, and have various applications in physics and mathematics.

### Usage

```

clifford(terms, coeffs=1)
is_ok_clifford(terms, coeffs)
as.clifford(x)
is.clifford(x)
nbits(x)
nterms(x)
## S3 method for class 'clifford'
dim(x)

```

### Arguments

<code>terms</code>	A list of integer vectors with strictly increasing entries corresponding to the basis vectors of the underlying vector space
<code>coeffs</code>	Numeric vector of coefficients
<code>x</code>	Object of class <code>clifford</code>

### Details

- Function `clifford()` is the formal creation mechanism for `clifford` objects. If `coeffs` is of length 1, it will be recycled (even if `terms` is empty, in which case the zero Clifford object is returned). Argument `terms` is passed through `list_modifier()`, so a zero entry is interpreted as `numeric(0)`
- Function `as.clifford()` is much more user-friendly and attempts to coerce a range of input arguments to `clifford` form
- Function `nbits()` returns the number of bits required in the low-level C routines to store the terms (this is the largest entry in the list of terms). For a scalar, this is zero and for the zero `clifford` object it (currently) returns zero as well although a case could be made for `NULL`
- Function `nterms()` returns the number of terms in the expression
- Function `is_ok_clifford()` is a helper function that checks for consistency of its arguments

## Examples

```
(x <- clifford(list(1,2,1:4),1:3)) # Formal creation method
(y <- as.1vector(4:2))
(z <- rcliff(include.fewer=TRUE))

terms(x+100)
coeffs(z)

## Clifford objects may be added and multiplied:

x + y
x*y
```

---

const

*The constant term of a Clifford object*

---

## Description

Get and set the constant term of a clifford object.

## Usage

```
const(C,drop=TRUE)
is.real(C)
## S3 replacement method for class 'clifford'
const(x) <- value
```

## Arguments

C, x	Clifford object
value	Replacement value
drop	Boolean, with default TRUE meaning to return the constant coerced to numeric, and FALSE meaning to return a (constant) Clifford object

## Details

Extractor method for specific terms. Function `const()` returns the constant element of a Clifford object. Note that `const(C)` returns the same as `grade(C, 0)`, but is faster. If `C` is a numeric vector, the first element is returned: any other elements are silently discarded, but this may change in future.

The R idiom in `const<-()` is slightly awkward:

```
> body(`const<-` .clifford`)
{
  stopifnot(length(value) == 1)
  x <- x - const(x)
  return(x + value)
}
```

The reason that it is not simply `return(x-const(x)+value)` or `return(x+value-const(x))` is to ensure numerical accuracy; see examples.

## Author(s)

Robin K. S. Hankin

## See Also

[grade](#), [clifford](#), [getcoeffs](#), [is.zero](#)

## Examples

```
X <- clifford(list(1,1:2,1:3,3:5),6:9)
X
X <- X + 1e300
X

const(X) # should be 1e300

const(X) <- 0.6
const(X) # should be 0.6, no numerical error

# compare naive approach:

X <- clifford(list(1,1:2,1:3,3:5),6:9)+1e300
X+0.6-const(X) # constant gets lost in the numerics

X <- clifford(list(1,1:2,1:3,3:5),6:9)+1e-300
X-const(X)+0.6 # answer correct by virtue of left-associativity

x <- 2+rcliff(d=3,g=3)
jj <- x*cliffconj(x)
is.real(jj*rev(jj)) # should be TRUE
```

---

dot-class	<i>Class “dot”</i>
-----------	--------------------

---

**Description**

The dot object is defined so that idiom like `.[x,y]` returns the commutator, that is,  $(x*y-y*x)/2$ . The factor of 2 ensures that `.[x,y] == x %X% y`.

The dot object is generated by running script `inst/dot.Rmd`, which includes some further discussion and technical documentation, and creates file `dot.rda` which resides in the `data/` directory.

**Arguments**

<code>x</code>	Object of any class
<code>i, j</code>	elements to commute
<code>...</code>	Further arguments to <code>dot_error()</code> , currently ignored

**Value**

Always returns an object of the same class as `xy`.

**Author(s)**

Robin K. S. Hankin

**Examples**

```
x <- rcliff()
y <- rcliff()
z <- rcliff()

.[x,.[y,z]] + .[y,.[z,x]] + .[z,.[x,y]] # Jacobi identity
```

---

drop	<i>Drop redundant information</i>
------	-----------------------------------

---

**Description**

Coerce scalar Clifford objects to numeric

**Usage**

```
drop(x)
drop_clifford(x)
```

**Arguments**

x                      Clifford object

**Details**

If its argument is a pure scalar clifford object, or the pseudoscalar, coerce to numeric. Scalar or pseudoscalar clifford objects are coerced to an *unnamed* numeric vector (of length 1). Checking for being the pseudoscalar requires that option `maxdim` be set.

Function `drop()` is generic, dispatching to helper function `drop_clifford()` for clifford objects. The logic of `drop_clifford()` prevents `is.pseudoscalar()` being called if `maxdim` is `NULL`.

**Note**

Many functions in the package take `drop` as an argument which, if `TRUE`, means that the function returns a dropped value.

**Author(s)**

Robin K. S. Hankin

**See Also**

**Examples**

```
drop(as.clifford(5))

const(rcliff())
const(rcliff(),drop=FALSE)
```

---

even

*Even and odd clifford objects*

---

**Description**

A clifford object is *even* if every term has even grade, and *odd* if every term has odd grade.

Functions `is.even()` and `is.odd()` test a clifford object for evenness or oddness.

Functions `evenpart()` and `oddpart()` extract the even or odd terms from a clifford object, and we write  $A_+$  and  $A_-$  respectively; we have  $A = A_+ + A_-$

**Usage**

```
is.even(C)
is.odd(C)
evenpart(C)
oddpart(C)
```

**Arguments**

C                    Clifford object

**Author(s)**

Robin K. S. Hankin

**See Also**

[grade](#)

**Examples**

```
A <- rcliff()
A == evenpart(A) + oddpart(A) # should be true
```

---

Extract.clifford            *Extract or Replace Parts of a clifford*

---

**Description**

Extract or replace subsets of cliffords.

**Usage**

```
## S3 method for class 'clifford'
C[index, ...,drop=FALSE]
## S3 replacement method for class 'clifford'
C[index, ...] <- value
coeffs(x)
coeffs(x) <- value
list_modifier(B)
getcoeffs(C, B)
## S3 method for class 'clifford'
Im(z)
## S3 method for class 'clifford'
Re(z)
```

**Arguments**

C, x, z            A clifford object  
index            elements to extract or replace  
value            replacement value  
B                A list of integer vectors, terms  
drop            Boolean: should constant clifford objects be coerced to numeric?  
...            Further arguments

## Details

Extraction and replacement methods. The extraction method uses `getcoeffs()` and the replacement method uses low-level helper function `c_overwrite()`.

In the extraction function `a[index]`, if `index` is a list, further arguments are ignored; if not, the dots are used. If `index` is a list, its elements are interpreted as integer vectors indicating which terms to be extracted (even if it is a `disord` object). If `index` is a `disord` object, standard consistency rules are applied. The extraction methods are designed so that idiom such as `a[coeffs(a)>3]` works.

For replacement methods, the standard use-case is `a[i] <- b` in which argument `i` is a list of integer vectors and `b` a length-one numeric vector; (replacement vectors of length greater than one are currently not implemented, whether or not they violate `disordR` discipline). Otherwise, to manipulate parts of a clifford object, use `coeffs(a) <- value`; `disord` discipline is enforced. Idiom such as `a[coeffs(a)<2] <- 0` is implemented experimentally, as syntactic sugar for `coeffs(a)[coeffs(a)<2] <- 0`. Replacement using a list-valued index, as in `A[i] <- value` uses an ugly hack if `value` is zero. Replacement methods are not yet finalised and not yet fully integrated with the `disordR` package.

Idiom such as `a[] <- b` follows the `spray` package. If `b` is a length-one scalar, then `coeffs(a) <- b` has the same effect as `a[] <- b`.

Functions `terms()` [see `term.Rd`] and `coeffs()` extract the terms and coefficients from a clifford object. These functions return `disord` objects but the ordering is consistent between them (an extended discussion of this phenomenon is presented in the **mvp** package). Note that `coeffs()` returns `numeric(0)` on the zero clifford object.

Function `coeffs<-()` (idiom `coeffs(a) <- b`) sets all coefficients of `a` to `b`. This has the same effect as `a[] <- b`.

Extracting or replacing a list with a repeated elements is usually a Bad Idea (tm). However, if option `warn_on_repeats` is set to `FALSE`, no warning will be given (and the coefficient will be the sum of the coefficients of the term; see the examples).

Function `getcoeffs()` is a lower-level helper function that lacks the succour offered by `[.clifford()]`. It returns a named numeric vector [not a `disord` object: the order of the elements is determined by the order of argument `B`]. Compare standard extraction, eg `a[index]`, which returns a clifford object. The names of the returned vector are determined by function `catterm()`.

Attempting to extract a coefficient of a term that includes a negative index will throw an error. The coefficient of a term not present in the Clifford object (including term with an index larger than indicated by `maxyterm()`) will return zero.

The index for the constant is formally `list(numeric(0))`, but this is a pain to type. Square bracket extraction and `getcoeffs()` have special dispensation for zero entries, which are translated by helper function `list_modifier()` to `numeric(0)` and listified if necessary. The upshot is that `x[0]` and `getcoeffs(x, 0)` work as expected, returning the constant.

Function `Im()` is a generic, which sets the real component of its argument to zero (as per the **onion** package). Function `Re()` is a convenience synonym for `const()`.

Vignette `getcoeffs` gives a more extended discussion of function `getcoeffs()`.

**Examples**

```

A <- clifford(list(1,1:2,1:3),1:3)
B <- clifford(list(1:2,1:6),c(44,45))

A[1,c(1,3,4)]

A[2:3, 4] <- 99
A[] <- B

X <- 5 + 6*e(1) -7*e(1:3) + 3*e(4:5)
X[0]          # special dispensation for zero
X[0,drop=TRUE] # coerce to numeric
X[list(0,1:3)]

getcoeffs(X,0)
getcoeffs(X,list(1,0,1:3))

# clifford(list(1,1:2,1:2),1:3) # would give a warning

options("warn_on_repeats" = FALSE)
clifford(list(1,1:2,1:2),1:3) # works; 1e1 + 5e_12

options("warn_on_repeats" = TRUE) # return to default behaviour.

```

---

grade

*The grade of a clifford object*

---

**Description**

The *grade* of a term is the number of basis vectors in it.

**Usage**

```

grade(C, n, drop=TRUE)
grade(C,n) <- value
grades(x)
gradesplus(x)
gradesminus(x)
gradeszero(x)

```

**Arguments**

C, x	Clifford object
n	Integer vector specifying grades to extract

value	Replacement value, a numeric vector
drop	Boolean, with default TRUE meaning to coerce a constant Clifford object to numeric, and FALSE meaning not to

### Details

A *term* is a single expression in a Clifford object. It has a coefficient and is described by the basis vectors it comprises. Thus  $4e_{234}$  is a term but  $e_3 + e_5$  is not.

The *grade* of a term is the number of basis vectors in it. Thus the grade of  $e_1$  is 1, and the grade of  $e_{125} = e_1e_2e_5$  is 3. The grade operator  $\langle \cdot \rangle_r$  is used to extract terms of a particular grade, with

$$A = \langle A \rangle_0 + \langle A \rangle_1 + \langle A \rangle_2 + \cdots = \sum_r \langle A \rangle_r$$

for any Clifford object  $A$ . Thus  $\langle A \rangle_r$  is said to be homogenous of grade  $r$ . Hestenes sometimes writes subscripts that specify grades using an overbar as in  $\langle A \rangle_{\bar{r}}$ . It is conventional to denote the zero-grade object  $\langle A \rangle_0$  as simply  $\langle A \rangle$ .

We have

$$\langle A + B \rangle_r = \langle A \rangle_r + \langle B \rangle_r \quad \langle \lambda A \rangle_r = \lambda \langle A \rangle_r \quad \langle \langle A \rangle_r \rangle_s = \langle A \rangle_r \delta_{rs}.$$

Function `grades()` returns an (unordered) vector specifying the grades of the constituent terms. Function `grades<-()` allows idiom such as `grade(x, 1:2) <- 7` to operate as expected [here to set all coefficients of terms with grades 1 or 2 to value 7].

Function `gradesplus()` returns the same but counting only basis vectors that square to +1, and `gradesminus()` counts only basis vectors that square to -1. Function `signature()` controls which basis vectors square to +1 and which to -1.

From Perwass, page 57, given a bilinear form

$$\langle \mathbf{x}, \mathbf{x} \rangle = x_1^2 + x_2^2 + \cdots + x_p^2 - x_{p+1}^2 - \cdots - x_{p+q}^2$$

and a basis blade  $e_A$  with  $A \subseteq \{1, \dots, p+q\}$ , then

$$\text{gr}(e_A) = |\{a \in A : 1 \leq a \leq p+q\}|$$

$$\text{gr}_+(e_A) = |\{a \in A : 1 \leq a \leq p\}|$$

$$\text{gr}_-(e_A) = |\{a \in A : p < a \leq p+q\}|$$

Function `gradeszero()` counts only the basis vectors squaring to zero (I have not seen this anywhere else, but it is a logical suggestion).

If the signature is zero, then the Clifford algebra reduces to a Grassmann algebra and products match the wedge product of exterior calculus. In this case, functions `gradesplus()` and `gradesminus()` return NA.

Function `grade(C, n)` returns a clifford object with just the elements of grade  $g$ , where  $g \%in\% n$ .

The zero grade term, `grade(C, 0)`, is given more naturally by `const(C)`.

Function `c_grade()` is a helper function that is documented at `Ops.clifford.Rd`.

**Note**

In the C code, “term” has a slightly different meaning, referring to the vectors without the associated coefficient.

[signature](#), [const](#)

**Examples**

```
a <- clifford(sapply(seq_len(7), seq_len), seq_len(7))
a
grades(a)
grade(a, 5)

signature(2, 2)
x <- rcliff()
drop(gradesplus(x) + gradesminus(x) + gradeszero(x) - grades(x))

a <- rcliff()
a == Reduce(`+`, sapply(unique(grades(a)), function(g){grade(a, g)}))
```

---

homog

*Homogenous Clifford objects*

---

**Description**

A clifford object is homogenous if all its terms are the same grade. A scalar (including the zero clifford object) is considered to be homogenous. This ensures that `is.homog(grade(C, n))` always returns TRUE.

**Usage**

```
is.homog(C)
```

**Arguments**

C                      Object of class clifford

**Note**

Nonzero homogenous clifford objects have a multiplicative inverse.

**Author(s)**

Robin K. S. Hankin

**Examples**

```
is.homog(rcliff())
is.homog(rcliff(include.fewer=FALSE))
```

---

horner

*Horner's method*

---

**Description**

Horner's method for Clifford objects

**Usage**

horner(P, v)

**Arguments**

P	A Clifford object
v	Numeric vector of coefficients

**Details**

Given a polynomial

$$p(x) = a_0 + a_1 + a_2x^2 + \cdots + a_nx^n$$

it is possible to express  $p(x)$  in the algebraically equivalent form

$$p(x) = a_0 + x(a_1 + x(a_2 + \cdots + x(a_{n-1} + xa_n)\cdots))$$

which is much more efficient for evaluation, as it requires only  $n$  multiplications and  $n$  additions, and this is optimal. The output of horner() depends on the signature().

**Note**

Horner's method is not as cool for Clifford objects as it is for (e.g.) multivariate polynomials or freealg objects. This is because powers of Clifford objects don't get more complicated as the power increases.

**Author(s)**

Robin K. S. Hankin

**Examples**

```
horner(1+e(1:3)+e(2:3) , 1:6)
```

```
rcliff() |> horner(1:4)
```

involution

*Clifford involutions*

**Description**

An *involution* is a function that is its own inverse, or equivalently  $f(f(x)) = x$ . There are several important involutions on Clifford objects; these commute past the grade operator with  $f(\langle A \rangle_r) = \langle f(A) \rangle_r$  and are linear:  $f(\alpha A + \beta B) = \alpha f(A) + \beta f(B)$ .

The *dual* is documented here for convenience, even though it is not an involution (applying the dual *four* times is the identity).

- The *reverse*  $A^\sim$  is given by `rev()` (both Perwass and Dorst use a tilde, as in  $\tilde{A}$  or  $A^\sim$ . However, both Hestenes and Chisholm use a dagger, as in  $A^\dagger$ . This page uses Perwass's notation). The *reverse* of a term written as a product of basis vectors is simply the product of the same basis vectors but written in reverse order. This changes the sign of the term if the number of basis vectors is 2 or 3 (modulo 4). Thus, for example,  $(e_1 e_2 e_3)^\sim = e_3 e_2 e_1 = -e_1 e_2 e_3$  and  $(e_1 e_2 e_3 e_4)^\sim = e_4 e_3 e_2 e_1 = +e_1 e_2 e_3 e_4$ . Formally, if  $X = e_{i_1} \dots e_{i_k}$ , then  $\tilde{X} = e_{i_k} \dots e_{i_1}$ .

$$\langle A^\sim \rangle_r = \langle \tilde{A} \rangle_r = (-1)^{r(r-1)/2} \langle A \rangle_r$$

Perwass shows that  $\langle AB \rangle_r = (-1)^{r(r-1)/2} \langle \tilde{B} \tilde{A} \rangle_r$

- The *Conjugate*  $A^\dagger$  is given by `Conj()` (we use Perwass's notation, def 2.9 p59). This depends on the signature of the Clifford algebra; see `grade.Rd` for notation. Given a basis blade  $e_{\mathbb{A}}$  with  $\mathbb{A} \subseteq \{1, \dots, p+q\}$ , then we have  $e_{\mathbb{A}}^\dagger = (-1)^m e_{\mathbb{A}}^\sim$ , where  $m = \text{gr}_-(\mathbb{A})$ . Alternatively, we might say

$$\langle \langle A \rangle_r \rangle^\dagger = (-1)^m (-1)^{r(r-1)/2} \langle A \rangle_r$$

where  $m = \text{gr}_-(\langle A \rangle_r)$  [NB I have changed Perwass's notation].

- The *main (grade) involution* or *grade involution*  $\hat{A}$  is given by `gradeinv()`. This changes the sign of any term with odd grade:

$$\langle \hat{A} \rangle_r = (-1)^r \langle A \rangle_r$$

(I don't see this in Perwass or Hestenes; notation follows Hitzer and Sangwine). It is a special case of grade negation.

- The *grade  $r$ -negation*  $A_{\bar{r}}$  is given by `neg()`. This changes the sign of the grade  $r$  component of  $A$ . It is formally defined as  $A - 2 \langle A \rangle_r$ , but function `neg()` uses a more efficient method. It is possible to negate all terms with specified grades, so for example we might have  $\langle A \rangle_{\overline{\{1,2,5\}}} = A - 2(\langle A \rangle_1 + \langle A \rangle_2 + \langle A \rangle_5)$  and the R idiom would be `neg(A, c(1, 2, 5))`. Note that Hestenes uses “ $A_{\bar{r}}$ ” to mean the same as  $\langle A \rangle_r$ .
- The *Clifford conjugate*  $\bar{A}$  is given by `cliffconj()`. It is distinct from conjugation  $A^\dagger$ , and is defined in Hitzler and Sangwine as

$$\overline{\langle A \rangle_r} = (-1)^{r(r+1)/2} \langle A \rangle_r.$$

- The *dual*  $C^*$  of a clifford object  $C$  is given by `dual(C, n)`; argument  $n$  is the dimension of the underlying vector space. Perwass gives  $C^* = CI^{-1}$  where  $I = e_1 e_2 \dots e_n$  is the unit pseudoscalar [note that Hestenes uses  $I$  to mean something different]. The dual is sensitive to the signature of the Clifford algebra *and* the dimension of the underlying vector space.

### Usage

```
## S3 method for class 'clifford'
rev(x)
## S3 method for class 'clifford'
Conj(z)
cliffconj(z)
neg(C,n)
gradeinv(C)
```

### Arguments

<code>C, x, z</code>	Clifford object
<code>n</code>	Integer vector specifying grades to be negated in <code>neg()</code>

### Author(s)

Robin K. S. Hankin

### See Also

[grade](#)

### Examples

```
x <- rcliff()
x
rev(x)

A <- rblade(g=3)
B <- rblade(g=4)
rev(A %^% B) == rev(B) %^% rev(A) # should be TRUE
rev(A * B) == rev(B) * rev(A) # should be TRUE
```

```
options(maxdim=8)
a <- rcliff(d=8)
dual(dual(dual(dual(a,8),8),8),8) == a # should be TRUE
options(maxdim=NULL) # restore default
```

---

lowlevel

*Low-level helper functions for clifford objects*

---

## Description

Helper functions for clifford objects, written in C using the STL map class.

## Usage

```
c_identity(L, p, m)
c_grade(L, c, m, n)
c_add(L1, c1, L2, c2, m)
c_multiply(L1, c1, L2, c2, m, sig)
c_power(L, c, m, p, sig)
c_equal(L1, c1, L2, c2, m)
c_overwrite(L1, c1, L2, c2, m)
c_cartan(L, c, m, n)
c_cartan_inverse(L, c, m, n)
```

## Arguments

L, L1, L2	Lists of terms
c1, c2, c	Numeric vectors of coefficients
m	Maximum entry of terms
n	Grade to extract
p	Integer power
sig	Two positive integers, $p$ and $q$ , representing the number of $+1$ and $-1$ terms on the main diagonal of quadratic form

## Details

The functions documented here are low-level helper functions that wrap the C code. They are called by functions like `clifford_plus_clifford()`, which are themselves called by the binary operators documented at `Ops.clifford.Rd`. The functions documented here are not really intended for day-to-day use.

Function `c_identity()` checks that the list of terms `L` is the same length as the vector coefficients `p`; if not, an error is given. Note that R function `clifford()` will recycle the coefficient vector if of length 1, so that `clifford(list(1,1:2),7)` works as expected (but `c_identity(list(1,1:2),7,2)` will throw an error).

Function `clifford_inverse()` is problematic as nonnull blades always have an inverse; but function `is.blade()` is not yet implemented. Blades (including null blades) have a pseudoinverse, but this is not implemented yet either.

**Value**

The high-level functions documented here return an object of class `clifford`. But don't use the low-level functions.

**Author(s)**

Robin K. S. Hankin

**See Also**

[Ops.clifford](#)

---

magnitude

*Magnitude of a clifford object*

---

**Description**

Following Perwass, the magnitude of a multivector is defined as

$$\|A\| = \sqrt{A * A}$$

Where  $A * A$  denotes the Euclidean scalar product `euclprod()`. Recall that the Euclidean scalar product is never negative (the function body is `sqrt(abs(euclprod(z)))`; the `abs()` is needed to avoid numerical roundoff errors in `euclprod()` giving a negative value).

**Usage**

```
## S3 method for class 'clifford'
Mod(z)
```

**Arguments**

`z` Clifford objects

**Note**

If you want the square,  $\|A\|^2$  and not  $\|A\|$ , it is faster and more accurate to use `euclprod(A)`, because this avoids a needless square root.

There is a nice example of scalar product at `rcliff.Rd`.

**Author(s)**

Robin K. S. Hankin

**See Also**

[Ops.clifford](#), [Conj](#), [rcliff](#)

**Examples**

```

Mod(rcliff())

# Perwass, p68, asserts that if A is a k-blade, then (in his notation)
# AA == A*A.

# In package idiom, A*A == A %star% A:

A <- rcliff()
Mod(A*A - A %star% A) # meh

A <- rblade()
Mod(A*A - A %star% A) # should be small

```

---

 minus

*Take the negative of a vector*

---

**Description**

Very simple function that takes the negative of a vector, here so that idiom such as `coeffs(z)[gradesminus(z)%%2 != 0] %<>% minus` works as intended (this taken from `Conj.clifford()`).

**Usage**

```
minus(x)
```

**Arguments**

`x` Any vector or disord object

**Value**

Returns a vector or disord

**Author(s)**

Robin K. S. Hankin

---

numeric\_to\_clifford    *Coercion from numeric to Clifford form*

---

### Description

Given a numeric value or vector, return a Clifford algebra element

### Usage

```
numeric_to_clifford(x)
as.1vector(x)
is.1vector(x)
scalar(x=1)
as.scalar(x=1)
is.scalar(C)
basis(n,x=1)
e(n,x=1)
```

### Arguments

x	Numeric vector
n	Integer specifying dimensionality of underlying vector space
C	Object possibly of class Clifford

### Details

Function `as.scalar()` takes a length-one numeric vector and returns a Clifford scalar of that value (to extract the scalar component of a multivector, use `const()`).

Function `is.scalar()` is a synonym for `is.real()` which is documented at `const.Rd`.

Function `as.1vector()` takes a numeric vector and returns the linear sum of length-one blades with coefficients given by `x`; function `is.1vector()` returns TRUE if every term is of grade 1.

Function `numeric_to_vector()` dispatches to either `as.scalar()` for length-one vectors or `as.1vector()` if the length is greater than one.

Function `basis()` returns a wedge product of basis vectors; function `e()` is a synonym. There is special dispensation for zero, so `e(0)` returns the Clifford scalar 1.

Function `antivector()` should arguably be described here but is actually documented at `antivector.Rd`.

C1 %X% C2
C1 %star% C2
C1 % % C2
C1 %euc% C2
C1 %o% C2
C1 %_|% C2
C1 %|_% C2

```

**Arguments**

e1, e2, C, C1, C2	Objects of class <code>clifford</code> or coerced if needed
x	Scalar, length one numeric vector
drop	Boolean, with default <code>TRUE</code> meaning to return the constant coerced to numeric, and <code>FALSE</code> meaning to return a (constant) Clifford object

**Details**

The function `Ops.clifford()` passes unary and binary arithmetic operators “+”, “-”, “\*”, “/” and “^” to the appropriate specialist function. Function `maxyterm()` returns the maximum index in the terms of its arguments.

The package has several binary operators:

Geometric product	$A*B = \text{geoprod}(A,B)$	$AB = \sum_{r,s} \langle A \rangle_r \langle B \rangle_s$
Inner product	$A \%.\% B = \text{cliffdotprod}(A,B)$	$A \cdot B = \sum_{\substack{r \neq 0 \\ s \neq 0}} \langle \langle A \rangle_r \langle B \rangle_s \rangle_{ s-r }$
Outer product	$A \%^\wedge B = \text{wedge}(A,B)$	$A \wedge B = \sum_{r,s} \langle \langle A \rangle_r \langle B \rangle_s \rangle_{s+r}$
Fat dot product	$A \%o\% B = \text{fatdot}(A,B)$	$A \bullet B = \sum_{r,s} \langle \langle A \rangle_r \langle B \rangle_s \rangle_{ s-r }$
Left contraction	$A \%_ \% B = \text{lefttick}(A,B)$	$A \rfloor B = \sum_{r,s} \langle \langle A \rangle_r \langle B \rangle_s \rangle_{s-r}$
Right contraction	$A \% _\% B = \text{righttick}(A,B)$	$A \lrcorner B = \sum_{r,s} \langle \langle A \rangle_r \langle B \rangle_s \rangle_{r-s}$
Cross product	$A \%X\% B = \text{cross}(A,B)$	$A \times B = \frac{1}{2} (AB - BA)$
Scalar product	$A \%star\% B = \text{star}(A,B)$	$A * B = \sum_{r,s} \langle \langle A \rangle_r \langle B \rangle_s \rangle_0$
Euclidean product	$A \%euc\% B = \text{eucprod}(A,B)$	$A \star B = A * B^\dagger$

In R idiom, the geometric product `geoprod(. , .)` has to be indicated with a “\*” (as in `A*B`) and so the binary operator must be `%*%`: we need a different idiom for scalar product, which is why `%star%` is used.

Because geometric product is often denoted by juxtaposition, package idiom includes `a \% b` for geometric product.

Binary operator `%dot%` is a synonym for `.\%`, which causes problems for `rmarkdown`.

Function `clifford_inverse()` returns an inverse for nonnull Clifford objects  $Cl(p, q)$  for  $p + q \leq 5$ , and a few other special cases. The functionality is problematic as nonnull blades always have an inverse; but function `is.blade()` is not yet implemented. Blades (including null blades) have a pseudoinverse, but this is not implemented yet either.

The *scalar product* of two clifford objects is defined as the zero-grade component of their geometric product:

$$A * B = \langle AB \rangle_0 \quad \text{NB: notation used by both Perwass and Hestenes}$$

In package idiom the scalar product is given by `A %star% B` or `scalprod(A,B)`. Hestenes and Perwass both use an asterisk for scalar product as in “`A * B`”, but in package idiom, the asterisk is reserved for geometric product.

**Note: in the package, `A*B` is the geometric product.**

The *Euclidean product* (or *Euclidean scalar product*) of two clifford objects is defined as

$$A \star B = A * B^\dagger = \langle AB^\dagger \rangle_0 \quad \text{Perwass}$$

where  $B^\dagger$  denotes Conjugate [as in `Conj(a)`]. In package idiom the Euclidean scalar product is given by `euclidprod(A,B)` or `A %euc% B`, both of which return `A * Conj(B)`.

Note that the scalar product  $A * A$  can be positive or negative [that is, `A %star% A` may be any sign], but the Euclidean product is guaranteed to be non-negative [that is, `A %euc% A` is always positive or zero].

Dorst defines the left and right contraction (Chisholm calls these the left and right inner product) as  $A \rfloor B$  and  $A \lrcorner B$ . See the vignette for more details.

Division, as in idiom `x/y`, is defined as `x*clifford_inverse(y)`. Function `clifford_inverse()` uses the method set out by Hitzer and Sangwine but is limited to  $p + q \leq 5$ .

The Lie bracket,  $[x, y]$  is implemented in the package using idiom such as `.[x,y]`, and this is documented at `dot.Rd`.

Many of the functions documented here use low-level helper functions that wrap C code. For example, `fatdot()` uses `c_fatdotprod()`. These are documented at `lowLevel.Rd`.

## Value

The high-level functions documented here return a `clifford` object. The low-level functions are not really intended for the end-user.

## Note

All the different Clifford products have binary operators for convenience including the wedge product `%^%`. However, as an experimental facility, the caret “`^`” returns either multiplicative powers [as in `A^3=A*A*A`], or a wedge product [as in `A^B = A %^% B = wedge(A,B)`] depending on the class of the second argument. I don’t see that “`A ^ B`” is at all ambiguous but OTOH I might withdraw it if it proves unsatisfactory for some reason.

Compare the **stokes** package, where multiplicative powers do not really make sense and  $A^B$  is interpreted as a wedge product of differential forms  $A$  and  $B$ . In **stokes**, the wedge product is the *sine qua non* for the whole package and needs a terse idiomatic representation (although there `A%^%B` returns the wedge product too).

**Using `%.%` causes severe and weird difficult-to-debug problems in markdown documents.**

## Author(s)

Robin K. S. Hankin

[dot](#)

## Examples

```

u <- rcliff(5)
v <- rcliff(5)
w <- rcliff(5)

u
v
u*v

u+(v+w) == (u+v)+w      # should be TRUE by associativity of "+"
u*(v*w) == (u*v)*w      # should be TRUE by associativity of "*"
u*(v+w) == u*v + u*w    # should be TRUE by distributivity

# Now if x,y are _vectors_ we have:

x <- as.1vector(sample(5))
y <- as.1vector(sample(5))
x*y == x%.%y + x%^%y
x %^% y == x %^% (y + 3*x)
x %^% y == (x*y-x*y)/2    # should be TRUE

# above are TRUE for x,y vectors (but not for multivectors, in general)

## Inner product "%.%" is not associative:
x <- rcliff(5,g=2)
y <- rcliff(5,g=2)
z <- rcliff(5,g=2)
x %.% (y %.% z) == (x %.% y) %.% z

## Other products should work as expected:

x %|_% y    ## left contraction
x %_|% y    ## right contraction
x %o% y     ## fat dot product
x ^ y      ## Experimental wedge product idiom, plain caret

```

---

print	<i>Print clifford objects</i>
-------	-------------------------------

---

**Description**

Print methods for Clifford algebra

**Usage**

```
## S3 method for class 'clifford'
print(x,...)
## S3 method for class 'clifford'
as.character(x,...)
catterm(a)
```

**Arguments**

x	Object of class <code>clifford</code> in the print method
...	Further arguments, currently ignored
a	Integer vector representing a term

**Note**

The print method does not change the internal representation of a `clifford` object, which is a two-element list, the first of which is a list of integer vectors representing terms, and the second is a numeric vector of coefficients. The print method has special dispensation for the zero clifford object.

The print method is sensitive to the value of options `separate` and `basissep`. If option `separate` is `FALSE` (the default), the method prints the basis blades in a compact form, as in “e\_134”. The indices of the basis vectors are separated with the value of option `basissep` which is usually `NULL`; but if  $n > 9$ , then setting option `basissep` to a comma (“,”) might look good as it will print e\_10,11,12 instead of e\_101112:

```
options("basissep" = ",")
```

If option `separate` is `TRUE`, the method prints the basis vectors separately, as in e10 e11 e12:

```
options("separate" = TRUE)
```

Function `catterm()` is a low-level helper function, used in the print method, coercion to character, and also in function `getcoeffs()` to set the names of its output. It takes an integer vector like `c(1,5,6)` and returns a representation of the corresponding basis blade, in this case “e\_156”. Function `catterm()` is where options `basissep` and `separate` are processed. Special dispensation is needed for length-zero vectors, for which the empty string is returned. This is needed to ensure that the constant term (which has a basis blade of `numeric(0)`) is treated appropriately. See also `list_modifier()` which deals with this issue.

**Author(s)**

Robin K. S. Hankin

**See Also**

[clifford](#)

**Examples**

```
a <- rcliff(9)
a # default print method incomprehensible

options("separate" = TRUE)
a # marginally better

options("separate" = FALSE)
options(basissep=",")
a # clearer; YMMV

options(basissep = NULL, maxdim=NULL) # restore default
```

---

pseudoscalar

*Coercion from numeric to Clifford form*

---

**Description**

Given a numeric value or vector, return a Clifford algebra element

**Usage**

```
pseudoscalar()
is.pseudoscalar(C)
```

**Arguments**

C                    Object possibly of class Clifford

**Details**

Function `pseudoscalar()` returns the unit pseudoscalar of dimensionality `option("maxdim")` and function `is.pseudoscalar()` checks for a Clifford object being a pseudoscalar. Note that these functions *require* `maxdim` to be set; otherwise they are meaningless.

Usually, one will set `option(maxdim)` at the start of a session, together with the signature. Then one might define `I <- pseudoscalar()` in the interests of compactness and legibility.

**Author(s)**

Robin K. S. Hankin

**See Also**

[getcoeffs](#), [numeric\\_to\\_clifford](#), [const](#)

**Examples**

```
options(maxdim=6)
I <- pseudoscalar()
is.pseudoscalar(I)
options(maxdim=NULL) # restore default
```

---

quaternion

*Quaternions using Clifford algebras*

---

**Description**

Converting quaternions to and from Clifford objects is not part of the package but functionality and a short discussion is included in `inst/quaternion_clifford.Rmd`.

**Details**

Given a quaternion  $a + bi + cj + dk$ , one may identify  $i$  with  $-e_{12}$ ,  $j$  with  $-e_{13}$ , and  $k$  with  $-e_{23}$  (the constant term is of course  $e_0$ ).

**Note**

A different mapping, from the quaternions to  $\text{Cl}(0, 2)$  is given at `signature.Rd`.

**Author(s)**

Robin K. S. Hankin

**See Also**

[signature](#)

---

rcliff *Random clifford objects*

---

### Description

Random Clifford algebra elements, intended as quick “get you going” examples of clifford objects

### Usage

```
rcliff(n=9, d=6, g=4, include.fewer=TRUE)
rcliff(n=100, d=20, g=10, include.fewer=TRUE)
rblade(d=7, g=3)
```

### Arguments

n	Number of terms
d	Dimensionality of underlying vector space
g	Maximum grade of any term
include.fewer	Boolean, with FALSE meaning to return a clifford object comprising only terms of grade g, and default TRUE meaning to include terms with grades less than g (including a term of grade zero, that is, a scalar)

### Details

Function `rcliff()` gives a quick nontrivial Clifford object, typically with terms having a range of grades (see ‘`grade.Rd`’); argument `include.fewer=FALSE` ensures that all terms are of the same grade. Function `rcliff()` is the same but returns a more complicated object by default.

Function `rblade()` gives a Clifford object that is a *blade* (see ‘`term.Rd`’). It returns the wedge product of a number of 1-vectors, for example  $(e_1 + 2e_2) \wedge (e_1 + 3e_5)$ .

Perwass gives the following lemma:

Given blades  $A_{\langle r \rangle}, B_{\langle s \rangle}, C_{\langle t \rangle}$ , then

$$\langle A_{\langle r \rangle} B_{\langle s \rangle} C_{\langle t \rangle} \rangle_0 = \langle C_{\langle t \rangle} A_{\langle r \rangle} B_{\langle s \rangle} \rangle_0$$

In the proof he notes in an intermediate step that

$$\langle A_{\langle r \rangle} B_{\langle s \rangle} \rangle_t * C_{\langle t \rangle} = C_{\langle t \rangle} * \langle A_{\langle r \rangle} B_{\langle s \rangle} \rangle_t = \langle C_{\langle t \rangle} A_{\langle r \rangle} B_{\langle s \rangle} \rangle_0.$$

Package idiom is shown in the examples.

### Note

If the grade exceeds the dimensionality,  $g > d$ , then the result is arguably zero; `rcliff()` returns an error.

**Author(s)**

Robin K. S. Hankin

**See Also**[term,grade](#)**Examples**

```
rcliff()
rcliff(d=3,g=2)
rcliff(3,10,7)
rcliff(3,10,7,include=TRUE)

x1 <- rcliff()
x2 <- rcliff()
x3 <- rcliff()

x1*(x2*x3) == (x1*x2)*x3 # should be TRUE

rblade()

# We can invert blades easily:
a <- rblade()
ainv <- rev(a)/scalprod(a)

zap(a*ainv) # 1 (to numerical precision)
zap(ainv*a) # 1 (to numerical precision)

# Perwass 2009, lemma 3.9:

A <- rblade(d=9,g=4)
B <- rblade(d=9,g=5)
C <- rblade(d=9,g=6)

grade(A*B*C,0)-grade(C*A*B,0) # zero to numerical precision

# Intermediate step

x1 <- grade(A*B,3) %star% C
x2 <- C %star% grade(A*B,3)
x3 <- grade(C*A*B,0)

max(x1,x2,x3) - min(x1,x2,x3) # zero to numerical precision
```

signature

*The signature of the Clifford algebra***Description**

Getting and setting the signature of the Clifford algebra

**Usage**

```
signature(p,q=0)
is_ok_sig(s)
showsig(s)
## S3 method for class 'sigobj'
print(x,...)
```

**Arguments**

s, p, q	Integers, specifying number of positive elements on the diagonal of the quadratic form, with s=c(p, q)
x	Object of class sigobj
...	Further arguments, currently ignored

**Details**

The signature functionality is modelled on the **lorentz** package; `clifford::signature()` operates in the same way as `lorentz::sol()` which gets and sets the speed of light. The idea is that both the speed of light and the signature of a Clifford algebra are generally set once, at the beginning of an R session, and subsequently change only very infrequently.

Clifford algebras require a bilinear form on  $\mathbb{R}^n \langle \cdot, \cdot \rangle$ , usually written

$$\langle \mathbf{x}, \mathbf{x} \rangle = x_1^2 + x_2^2 + \dots + x_p^2 - x_{p+1}^2 - \dots - x_{p+q}^2$$

where  $p + q = n$ . With this quadratic form the vector space is denoted  $\mathbb{R}^{p,q}$  and we say that  $(p, q)$  is the *signature* of the bilinear form  $\langle \cdot, \cdot \rangle$ . This gives rise to the Clifford algebra  $C_{p,q}$ .

If the signature is  $(p, q)$ , then we have

$$e_i e_i = +1 \text{ (if } 1 \leq i \leq p), -1 \text{ (if } p + 1 \leq i \leq p + q), 0 \text{ (if } i > p + q).$$

Note that  $(p, 0)$  corresponds to a positive-semidefinite quadratic form in which  $e_i e_i = +1$  for all  $i \leq p$  and  $e_i e_i = 0$  for all  $i > p$ . Similarly,  $(0, q)$  corresponds to a negative-semidefinite quadratic form in which  $e_i e_i = -1$  for all  $i \leq q$  and  $e_i e_i = 0$  for all  $i > q$ .

A strictly positive-definite quadratic form is specified by infinite  $p$  [in which case  $q$  is irrelevant], and `signature(Inf)` implements this. For a strictly negative-definite quadratic form we would have  $p = 0, q = \infty$  which would be `signature(0, Inf)`.

If we specify  $e_i e_i = 0$  for all  $i$ , then the operation reduces to the wedge product of a Grassmann algebra. Package idiom for this is to set  $p = q = 0$  with `signature(0,0)`, but this is not recommended: use the **stokes** package for Grassmann algebras, which is much more efficient and uses nicer idiom.

Function `signature(p,q)` returns the signature invisibly; but setting option `show_signature` to `TRUE` makes `signature()` have the side-effect of calling `showsig()`, which changes the default prompt to display the signature, much like `showSQL` in the **lorentz** package. There is special dispensation for “infinite”  $p$  or  $q$ .

Calling `signature()` [that is, with no arguments] returns an object of class `sigobj` with elements corresponding to  $p$  and  $q$ . The `sigobj` class ensures that a near-infinite integer such as `.Machine$integer.max` will be printed as “Inf” rather than, for example, “2147483647”.

Function `is_ok_sig()` is a helper function that checks for a proper signature. If we set `signature(p,q)`, then technically  $n > p + q$  implies  $e_n^2 = 0$ , but usually we are not interested in  $e_n$  when  $n > p + q$  and want this to be an error. Option `maxdim` specifies the maximum value of  $n$ , with default `NULL` corresponding to infinity. If  $n$  exceeds this, `is_ok_sig()` throws an error. Note that it is fine to have `maxdim > p+q` [and indeed this is useful in the context of dual numbers]. This option is intended to be a super-strict safety measure.

```
> e(6)
Element of a Clifford algebra, equal to
+ 1e_6
> options(maxdim=5)
> e(5)
Element of a Clifford algebra, equal to
+ 1e_5
> e(6)
Error in is_ok_clifford(terms, coeffs) : option maxdim exceeded
```

### Author(s)

Robin K. S. Hankin

### Examples

```
signature()

e(1)^2
e(2)^2

signature(1)
e(1)^2
e(2)^2 # note sign

signature(3,4)
sapply(1:10,function(i){drop(e(i)^2)})

signature(Inf) # restore default
```

```

# Nice mapping from Cl(0,2) to the quaternions (loading clifford and
# onion simultaneously is discouraged):

# library("onion")
# signature(0,2)
# Q1 <- rquat(1)
# Q2 <- rquat(1)
# f <- function(H){Re(H)+i(H)*e(1)+j(H)*e(2)+k(H)*e(1:2)}
# f(Q1)*f(Q2) - f(Q1*Q2) # zero to numerical precision
# signature(Inf)

```

---

summary.clifford

*Summary methods for clifford objects*

---

## Description

Summary method for clifford objects, and a print method for summaries.

## Usage

```

## S3 method for class 'clifford'
summary(object, ...)
## S3 method for class 'summary.clifford'
print(x, ...)
first_n_last(x)

```

## Arguments

object, x	Object of class clifford
...	Further arguments, currently ignored

## Details

Summary of a clifford object. Note carefully that the “typical terms” are implementation specific. Function `first_n_last()` is a helper function.

## Author(s)

Robin K. S. Hankin

## See Also

[print](#)

**Examples**

```
summary(rcliff())
```

---

term

*Deal with terms*

---

**Description**

By *basis vector*, I mean one of the basis vectors of the underlying vector space  $R^n$ , that is, an element of the set  $\{e_1, \dots, e_n\}$ . A *term* is a wedge product of basis vectors (or a geometric product of linearly independent basis vectors), something like  $e_{12}$  or  $e_{12569}$ . Sometimes I use the word “term” to mean a wedge product of basis vectors together with its associated coefficient: so  $7e_{12}$  would be described as a term.

From Perwass: a *blade* is the outer product of a number of 1-vectors (or, equivalently, the wedge product of linearly independent 1-vectors). Thus  $e_{12} = e_1 \wedge e_2$  and  $e_{12} + e_{13} = e_1 \wedge (e_2 + e_3)$  are blades, but  $e_{12} + e_{34}$  is not.

Function `rblade()`, documented at ‘`rcliff.Rd`’, returns a random blade.

Function `is.blade()` is not currently implemented: there is no easy way to detect whether a Clifford object is a product of 1-vectors.

**Usage**

```
terms(x)
is.blade(x)
is.basisblade(x)
```

**Arguments**

x                    Object of class `clifford`

**Details**

- Functions `terms()` and `coeffs()` are the extraction methods. These are unordered vectors but the ordering is consistent between them (an extended discussion of this phenomenon is presented in the `mvp` package).
- Function `term()` returns a clifford object that comprises a single term with unit coefficient.
- Function `is.basisterm()` returns TRUE if its argument has only a single term, or is a nonzero scalar; the zero clifford object is not considered to be a basis term.

[clifford,rblade](#)

**Examples**

```
x <- rcliff()
terms(x)

is.basisblade(x)

a <- as.1vector(1:3)
b <- as.1vector(c(0,0,0,12,13))

a %% b # a blade
```

---

 zap

*Zap small values in a clifford object*

---

**Description**

Generic version of `zapsmall()`

**Usage**

```
zap(x, drop=TRUE, digits = getOption("digits"))
```

**Arguments**

<code>x</code>	Clifford object
<code>drop</code>	Boolean with default TRUE meaning to coerce the output to numeric with <code>drop()</code>
<code>digits</code>	number of digits to retain

**Details**

Given a clifford object, coefficients close to zero are ‘zapped’, i.e., replaced by ‘0’ in much the same way as `base::zapsmall()`.

The function should be called `zapsmall()`, and dispatch to the appropriate base function, but I could not figure out how to do this with S3 (the docs were singularly unhelpful) and gave up.

Note, this function actually changes the numeric value, it is not just a print method.

**Author(s)**

Robin K. S. Hankin

**Examples**

```

a <- clifford(sapply(1:10, seq_len), 90^(1:10))
zap(a)
options(digits=3)
zap(a)

a-zap(a) # nonzero

B <- rblade(g=3)
mB <- B*rev(B)
zap(mB)
drop(mB)

```

---

zero

*The zero Clifford object*

---

**Description**

Dealing with the zero Clifford object presents particular challenges. Some of the methods need special dispensation for the zero object.

**Usage**

```
is.zero(x)
```

**Arguments**

x                    Clifford object

**Details**

To test for a Clifford object's being zero, use `is.zero()`. Idiom such as `x==0` will work irregardless, but sometimes one might prefer the functional form for stylistic reasons.

To create the zero object *ab initio*, use

```
clifford(list(), numeric(0))
```

although note that `scalar(0)` will work too.

**Note**

The coefficient of the zero clifford object, as in `coeff(scalar(0))`, is `numeric(0)` (but note that `1 + NULL` also returns `numeric(0)`).

Function `is.zero()` is problematic if another package which also has an `is.zero()` generic is loaded, for this will mask `clifford::is.zero()`. Specifically, the **jordan** package includes `jordan::is.zero()` and the two do not play nicely together.
